

Module Summary

In this module, you learned that:

Branches are used to isolate changes to code. When the changes are complete, they can be merged back into the main branch.

Repositories can be cloned to make it possible to work locally, then sync changes back to the original.

Repositories can be forked to be used as a base for a new project, or so that the developer can work independently.

A Pull Request (PR) can be submitted to have your changes reviewed and merged.

Large projects include people working in different roles:

Developer – creates code

Integrator – manages changes made by developers

Repository Administrator – configures and maintains access to the repository
